1 Single Sign On

Clinicians charting in their Electronic Health Record (EHR) system often find use for quickly viewing the maternal-fetal surveillance strip, as well as viewing or modifying annotations to this strip. To that end, PeriWatch Surveillance (PWS) has developed a single sign-on (SSO) integration whereby the user of an outside charting system may launch a special PWS surveillance screen without need of authenticating to PWS. This process and the enabling mechanism are described below.

1.2 Design Detail

Users of an EHR wishing to launch the PWS SSO integration will be provided a launch link, button, or other mechanism by the host EHR system. The host EHR system will launch an executable, the Message Dispatcher, in one of two modes:

1.2.3 Command Line Invocation using Message Dispatcher

One time use where the launch information is sent via command line. The Message Dispatcher then calls the Launch Service to pass the message along. In this case, there will be a launch per use of SSO launch. The command-line arguments contain the context and authentication required to successfully launch a relevant session of PWS.

1.2.4 File Watch Invocation

PeriWatch supports file-watch SSO mode, where the EHR can drop a file in a predesignated area indicating the user actions like Login, Logout and Patient Switch. These actions will be translated into appropriate PeriWatch launch messages and sent to the Launch Service. The files contain the context and authentication, in a predefined format, required to successfully launch a relevant session of PWS.

The Message Dispatcher resides on and is invoked from a central server and will communicate with a Launch Service on the PWS Server, The PWS server informs a resident and always-running Message Receiver on the user's client workstation. The Message Receiver already has registered with the PWS server using the value in the environment variable COMPUTERNAME.

The Message Receiver, upon receiving the encoded instructions, will launch PWS on the client workstation in a special windowed session, affect a login, and automatically display the surveillance strip of the patient indicated by the EHR at time of launch.

Command Line Invocation using PeriWatch Surveillance Client

PeriWatch Surveillance application is launched using command line arguments from the EHR. The command-line arguments contain the context and authentication required to successfully launch a relevant session of PWS.

1.2.5 Web Invocation

PeriWatch supports SSO launching from a web EHR using arguments sent in the URL. The arguments contain the context and authentication required to successfully launch a relevant session of PWS.

1.3 Invocation modes

Fax: 877-327-0084

1.4 User Mapping configuration:

PWS usernames may differ from those of the partner-EHR. To accommodate such configuration, PWS provides a real-time translation service (step four above), whereby EHR userIDs are translated during the process of SSO launch. This service also applies to interfacing of, e.g., annotations inbound to PWS from the partner-EHR.

Users at configured sites will need to provide the PWS Integrations Team representative with a list of users authorized to use the SSO feature. Typically, this takes the form of an Excel spreadsheet with two columns:

EHRuserID1 PWSuserID1
EHRuserID2 PWSuserID1
EHRuserID3 PWSuserID2

Note that multiple EHR userIDs may be mapped to a single PWS userID. Upon receipt of a launch request (or interface message) containing EHRuserIDx, PWS agents will query a database table for the corresponding PWS userID and perform an inline substitution.

Maintenance of this lookup table requires submission of new userID pairs to the PWS Integrations Team.

1.5 Installation/Configuration Detail

1) Obtain a copy of the Message Dispatcher files from a configured PWS Server. A server that has already been upgraded and set up for operation of the PeriWatch system.
2) The database is updated with user cross-mapping.
3) For the command line invocation using Message Dispatcher implementation nothing further must be done to the Message Dispatcher, other than having it available for launch by the EHR software when a button is clicked on the EHR software by the user.
4) Changes for the file-watch invocation on the PWS server side:
    a. The location of the directory where the files will be deposited by the EHR software.
    b. Whether there will be one instance of Message Dispatcher software running for the entire EHR application server or not. This decision is necessary because with the file-based mode the Message Dispatcher must run continuously to react to file creation.
    c. The File based approach requires that the hostname be available so that messages can be embedded. In the case that there is only one instance of Message Dispatcher running for multiple EHR sessions, the hostname would have to be communicated via either the filename or embedded in the directory name that is being watched (perhaps one directory per hostname).

    After all these decisions are made PeriGen operations and Tech Support will set up the Launch Service configurations appropriately in a custom configuration file residing on the PeriWatch Server. The Message Dispatcher has been modified to request and use this configuration and set itself up appropriately.

5) The message receiver is pushed to client workstations.
6) Message Receiver configured to restart on startup of workstations.

2 Maternal Interface Specification

The purpose of this section is to outline the PeriWatch Surveillance (**PWS**) expectations for HL7 message exchange with other systems. This document should form the foundation for interface design discussions and presumes prior knowledge of the Health Level Seven (**HL7**) messaging standard; details available at http://www.hl7.org.

With this version of PeriWatch Surveillance, the following logical datasets are expected to be in scope for each implementation of the system. Specific scope is to be determined during joint clinical workflow mapping exercise. Please refer to detail mapping templates in the appendix:

- ADT Inbound
- Results (ORU)
    - Documented results (Inbound/Outbound)
    - Labs (Inbound)
    - Outcomes (Inbound)
- Meds Inbound (RAS)

2.2 Communications

The PWS integrations engine resides on PWS training and production application servers, there sharing server IPs, network domain authorization/restrictions, and server hardware and database with the related application. As hardware and database are shared between application and integrations engine, PWS expresses strong preference towards the configuration of a **client-side filter**, where possible only passing messages related to existing or potential PWS patients to our engine for consideration and consumption. Often this filtering is accomplished by logic parsing PV1.3.1, passing messages only for patients with an assigned location of (e.g.) LND, LDRP, and/or OP OB Clinic; specific implementation of these filters is at client discretion. Additional requisite filtering may be required; details below where relevant.

Interface messaging occurs across TCP/IP connections. Our standard implementation port for incoming messages is **17676**. Outbound message destinations are expected to be the IP and port of a receiving interface engine; however, data may also be placed on a local file structure in various formats for collection at client preference.

Splitting of inbound message types occurs within the engine, and therefore messages should be collected at client systems and transmitted to PWS in a unitary stream where multiple system are involved (e.g., collect ADT, Lab, and Pharmacy messages for serial transmission to PWS on port 17676). Due to the loosely-coupled nature of the integrations engine with the application, messages need not be properly sequenced to be properly processed (e.g., reception of a lab message for a patient for which we have not yet received an ADT message is acceptable; reception of an ADT update message prior to reception of an ADT admit message is acceptable).

PWS is configured for serialized/bimodal message handling, transmitting or waiting for reception of acknowledgment messages immediately after message reception. Failed transmissions will retry or wait for retry until five attempts have passed, then closing the port and marking the route in error.

The low-level format of the HL7 data stream adheres to standard:

100 Regency Forest Drive Suite 200
Cary, North Carolina 27518

Phone: 855-236-4353
Fax: 877-327-0084

<SB>dddd**<EB><CR>**

…where **<SB>** is the start block character (1 byte ASCII <VT>, 0x0B),
dddd represents the HL7 message data stream,
<EB> is the end block character (1 byte ASCII <FS>, 0x1C), and
<CR> is the carriage return character (0x0D).

2.3 Charting Interface Description

Where a typical downstream ancillary will react to the reception of an ADT^A01 message by admitting that patient to their census, PWS will not take any action – instead the message contents are placed in a pool of data from which a user can draw information during a manual admission into the application. Similarly, pharmacy inbound messages are primarily for pre-population of medication information when users document an administration in our application. As this is a deviation from common expectation, feel free to ask for more detail.

HL7 Message Definitions

The PWS interface standard adheres to the published HL7 standards for any v2.x message type. Valid transmitted message segments which are not mentioned in the following message definitions are ignored by our application.

Message delimiters adhere to standard: |,^,&,~, and \ being reserved characters to delimit fields, components, subcomponents, repeating fields, and escaped characters (respectively).

PWS currently has the capacity to process inbound HL7 messages pertaining to registration (ADT), lab results (ORU), and Pharmacy messages (RDS, RDE, and RAS). Inbound data from host EHR systems are accepted as specially formatted ORU unsolicited result (R01) messages and/or inside OBX message segments appended to ADT messages. PWS also has facilities for the export of vitals and annotations, as well as metadata surrounding discharge and audit reporting. Provision of additional inbound or outbound message exchange is outside the scope of this document.

The following sections define the required and optional components of PWS HL7 messages. Indentations denote logical message sub-blocks; fields in curly braces (**{}**) may repeat, those in square brackets (**[]**) are optional per specification.

Message Structures

ADT^A0{1,2,3,4,5,8}	Admit, Transfer, Discharge, Registration, PreAdmit, Update
MSH	Message Header
EVN	Event Type
PID	Patient Identifier
NK1	Next-of-Kin / Emergency Contact
PV1	Patient Visit Information
[{ **PV2** }]	Additional Patient Visit Information

[{ **OBX** }]	Observation Segments
[{ **AL1** }]	Patient Allergy Information
[{ **DG1** }]	Patient Diagnoses

Admit, Discharge, Transfer (ADT)
PWS only processes received Admit, Transfers, Discharges, Registration, Pre-Admit, and Update (A01, A02, A03, A04, A05, and A08, respectively) messages.

A06, A07, A11 and A12 messages can be received/processes after being converted to appropriate message type (See below). All other message types are ignored and should be filtered from transmission.

Auto ADT, HL7 Trigger	Note
A06 - O/P to I/P	Sites to convert to an A02
A07 - I/P to O/P	Sites to convert to an A02
A11 - Cancel/Undo Admit	Sites to Convert to an A03
A12 - Cancel/Undo Transfer	Sites to Convert to an A02

Please see Appendix II for list of ADT fields transmitted to PWS.

ADT Example

The following section describes the expected behavior of a “standard” sample of ADT and Lab HL7 messages.

The following message was run through the interface engine into PWS (message formatted for legibility):

```
MSH|^~\\&|SendApp|SendFac|RecvApp|RecvFac|201101010001||ADT^A08|ADT201947277|P|2.3|||AL||||
PID|1||123456789||LASTNAME^FIRSTNAME||200112311259|M||WHITE|1 MAIN
   STREET^^TRUSTYVILLE^DC^20202||(202)202-0202^^^^^202^2020202||SIGN|SINGLE|NO PREFERENCE OF
   RELIGION|987654321|111-22-3333||||||||||
NK1|1|LASTNAME^JOHN|BRO|2 MAIN STREET^^TRUSTYVILLE^DC^20202|(202)2020203^^^^^202^2020204
PV1|1|I|UNIT^ROOM^BED^.||||001^DOCTOR^ATTENDING|002^DOCTOR^REFERRING|003^DOCTOR^CONSULTING|
   SERVICE||||ADMITSOURCE (e.g., ED)|||004^DOCTOR^ADMITTING|
```

To review the application’s consumption of this message:

- Open the PWS application,
- Sign in, and
- Navigate to the census screen:

- Select a bed into which you can admit the patient and click on “Admission” (as shown above).

- Search for your patient based on some known value (above, searching for “1” as part of the Name, MRN, or DateTime)
- Click “Search”
- In the resulting list, patients whose information has been obtained from inbound HL7 ADT messages will have an ***** in the “HL7” column, as above. Select the desired patient.

- The census screen will now have your patient listed, as shown in the screen clip above. Selecting that patient and clicking on “Admission” will open the following screen:

- Notice the fields populated in the screen above; comparing them against the HL7 message at the top of this document, the data source and destination are apparent.
- Further data is found elsewhere; select again the patient from the census and click “Chart”

- Selecting “Prenatal“ reveals the following screen with imported data:

The majority of the Obstetric Admitting and Prenatal records can be populated via the HL7 interface. The above describes the “standard” capabilities of the interface, if additional pre-population is desired please contact your interfaces representative or PWS project manager.

100 Regency Forest Drive Suite 200
Cary, North Carolina 27518

Phone: 855-236-4353
Fax: 877-327-0084

Outcomes Data

Mapping outcomes data is required in order to provide meaningful reports mapping early warning trends detected by the Surveillance/Vigilance platform and actual baby/maternal outcomes data elements such as delivery mode, APGAR scores etc.
Please refer to the EMR HL7 mapping template for the list of all ideal outcomes fields that could be relevant for effective correlation and reporting. It is possible that some fields are not readily available in the source system in which case they cannot be mapped. The scope is to be decided in collaboration with PeriGen clinical and interface team.

Laboratory Results
Results are received in unsolicited observation (ORU^R01) messages from LIS systems. This message type is reused for subsequent interface functionality; absent any requisite (and later-described) distinguishing information, received ORU^R01 messages are presumed to be laboratory observations/results.

ORU^R01	Unsolicited Results
MSH	Message Header
PID	Patient Identifier
PV1	Patient Visit Information
ORC	Common Order
{	
OBR	Observation Request
{	
OBX	Observation / Result
[{ **NTE** }]	Notes and Comments
[**SPM**]	Specimen
}	
}	

The following table outlines the default set of labs of interest to drive the analytics in the Vigilance platform:

LABs	**Urine**	**Microbiology**
WBC	Protein/Creatinine Ratio	Group B strep
Hemoglobin	Protein	Blood Cultures
HCT		
Differential		
creatinine		
ast		

alt		
LDH

NTE|1||****Comment Here****|
```

The PID segment of the passed message must match the MRN, first and last name, and date-of-birth of a patient who has either been manually admitted into PWS or for whom an ADT message exists and has been or will be sent to PWS. Upon arrival of a lab result message for an admitted patient, the census will show an 'L' next to the patient in the "Interface" column:

- Click on this "L" to show the Laboratory Results screen:

Phone: 855-236-4353
Fax: 877-327-0084

Inbound Annotations
Inbound annotations are expected according to the previously described ORU^R01 message container.

Annotations themselves are to be passed in OBX segments (which may repeat). An annotation's unique identifiers are the patient's medical record number, the datetime of the annotation (with resolution fixed at "second", 120100.000 and 120100.999 would be interpreted as occurring at the same time), and the field prefix.

OBX|n||ANNOTATION EXAMPLE||SOME TEXT HERE.||||||F|||20121212121202||USER

…becomes a new annotation by user at 12:12:02 12Dec12 – "ANNOTATION EXAMPLE: SOME TEXT HERE."

DateTime of the annotation must be localtime of the PWS server, as we perform an internal conversion to UTC based on the PWS application's server time.

Inbound Annotation OBX Segment definition (all fields are required):

Outbound Vitals and Annotations
Outbound vitals and annotations are transmitted utilizing the previously described ORU^R01 container. OBR.4.2 will contain either "Vitals" or "Annotation", to differentiate the message contents.

For outbound vitals, OBX.3 will contain the vital sign being detailed; OBX.5 will hold the value and OBX.6 the unit – e.g.,

OBX|2|NM|NIBPSystolic||118|^mmHg|||||

Available vital signs include:

- Maternal Heart Rate
- SpO_2
- Maternal Mean, Systolic, and Diastolic Blood Pressure

Outbound annotations are similarly formatted, with OBX.3 equaling "Annotation" for all, and OBX.5 containing the annotation – e.g.,

OBX_n			Observation / Result
.3.1	Field Prefix	**.14**	Date/Time of the Annotation
$.5_0$	Annotation Text	**$.16_0.1$**	Responsible Observer ID
.11	Insert Mode { F = New, C = Update, D = Delete }		

OBX||TX|Annotation||Strip evaluated by RN.

Please see Appendix I for list of Annotations transmitted from PWS.

100 Regency Forest Drive Suite 200
Cary, North Carolina 27518

Phone: 855-236-4353
Fax: 877-327-0084

Outbound Dynamic Data Distribution (3D) Report Metadata

Outbound dynamic data distribution metadata messages are transmitted utilizing the previously described ORU^R01 container.
Please see **Appendix I** for list of Uterine Fetal Assessment, Cervical Exam transmitted from PWS

Segment and Field Definitions

The following tables describe fields directly consumed by PWS. The intention of this section is to describe which fields are actually and directly mapped into (or out of) the PWS application. Fields required by the HL7 standard specification are still required for a message to be considered valid: omission of a field otherwise required by the HL7 standard specification from tables below indicates only that it is otherwise ignored by the PWS interface engine logic.

Unless otherwise noted, any additional subfield breakdowns will default to the first segment (e.g., if XXX.3.2 is noted in the table below but a given message defines subfields within XXX.3.2, XXX.3.2.1 will be utilized by default). If a field may repeat per specification, this field will be notated within the table by either a subscript **0** or **n;** indicating our use of only the first of the repeats and ignoring all subsequent fields or processing all passed repeats, respectively. Thus $AL1_n.5_0$ indicates that all passed allergy segments are processed, but that only the first .5 segment is considered for each AL1 – any subsequent .5 segments in a given AL1 message would be ignored.

All fields are considered of type **String** save **DateTime** fields, which are considered strings but parsed into MM/DD/YYYY HH:MM:SS.

3 PeriWatch Newborn Interface Specification

The purpose of this document is to outline the PeriWatch Surveillance (**PWS**) expectations for HL7 message exchange with other systems. This document should form the foundation for interface design discussions and presumes prior knowledge of the Health Level Seven (**HL7**) messaging standard; details available at http://www.hl7.org.

3.2 Communications

The PWS integrations engine resides on PWS training and production application servers, there sharing server IPs, network domain authorization/restrictions, and server hardware and database with the related application. As hardware and database are shared between application and integrations engine, PWS expresses strong preference towards the configuration of a **client-side filter**, where possible only passing messages related to existing or potential PWS patients to our engine for consideration and consumption. Often this filtering is accomplished by logic parsing PV1.3.1, passing messages only for patients with an assigned location of (e.g.) LDRP, NICU; specific implementation of these filters is at client discretion. Additional requisite filtering may be required; details below where relevant.

Interface messaging occurs across TCP/IP connections. Our standard implementation port for incoming messages is **17676**.

Splitting of inbound message types occurs within the engine, and therefore messages should be collected at client systems and transmitted to PWS in a unitary stream where multiple systems are involved (e.g., collect ADT and Lab messages for serial transmission to PWS on port 17676). Due to the loosely-coupled nature of the integrations engine with the application, messages need not be properly sequenced to be properly processed (e.g., reception of a lab message for a patient for which we have not yet received an ADT message is acceptable; reception of an ADT update message prior to reception of an ADT admit message is acceptable).

PWS is configured for serialized/bimodal message handling, transmitting or waiting for reception of acknowledgment messages immediately after message reception/transmission. Failed transmissions will retry or wait for retry until five attempts have passed, then closing the port and marking the route in error.

The low level format of the HL7 data stream adheres to standard:

<SB>dddd**<EB><CR>**

…where **<SB>** is the start block character (1 byte ASCII <VT>, 0x0B),
dddd represents the HL7 message data stream,
<EB> is the end block character (1 byte ASCII <FS>, 0x1C), and
<CR> is the carriage return character (0x0D).

3.3 Charting Interface Description

Where a typical downstream ancillary will react to the reception of an ADT^A01 message by admitting that patient to their census, PWS will not take any action – instead the message contents are placed in a pool of data from which a user can draw information during a manual admission into the application. As this is a deviation from common expectation, feel free to ask for more detail.

3.4 HL7 Message Definitions

The PWS interface standard adheres to the published HL7 standards for any v2.x message type through v2.6. Valid transmitted message segments which are not mentioned in the following message definitions are ignored by our application.

Message delimiters adhere to standard: |,^,&,~, and \ being reserved characters to delimit fields, components, subcomponents, repeating fields, and escaped characters (respectively).

PeriWatch Newborn currently has the capacity to process inbound HL7 messages pertaining to registration (ADT) and lab results (ORU). Provision of additional inbound or outbound message exchange is outside the scope of this document.

The following sections define the required and optional components of PWS HL7 messages. Indentations denote logical message sub-blocks; fields in curly braces (**{}**) may repeat, those in square brackets (**[]**) are optional per specification.

3.5 Message Structures

ADT^A0{1,4,5,8}	Admit, Registration, PreAdmit, Update
MSH	Message Header
EVN	Event Type
PID	Patient Identifier
NK1	Next-of-Kin / Emergency Contact
PV1	Patient Visit Information
[{ **PV2** }]	Additional Patient Visit Information
[{ **OBX** }]	Observation Segments
[{ **AL1** }]	Patient Allergy Information
[{ **DG1** }]	Patient Diagnoses

Admit, Discharge, Transfer (ADT)
PWS only processes received Admit, Registration, Pre-Admit, and Update (A01, A04, A05, and A08, respectively) messages; all others are ignored and should be filtered from transmission. PWS does not transmit any ADT messages.

3.6 ADT Example

The following message was run through the interface engine into PWS (message formatted for legibility):

```
MSH|^~\\&|SendApp|SendFac|RecvApp|RecvFac|201101010001||ADT^A08|ADT201947277|P|2.3|||AL||||
PID|1||123456789||LASTNAME^FIRSTNAME||200112311259|M||WHITE|1 MAIN

   OUT/INPATIENT|AlternateVisitNo||||||||||||||||||||||||||201101010002||||||||005^NURSE^ATTENDING
```

To review the application's consumption of this message:

- Open the PeriWatch Newborn application,
- Sign in, and
- Navigate to the census screen.

- Select “Admit” from the lower-left, then “Browse pending interface admissions”.

- Search for your patient based on some known value (above, searching for “1” as part of the Name, MRN, or DateTime); if you do not want to constrain the search by Baby’s Admission Date, you must select the text in the field and hit “Delete” or “Backspace” to clear the contents.
- Click “Search”

100 Regency Forest Drive Suite 200
Cary, North Carolina 27518

Phone: 855-236-4353
Fax: 877-327-0084

- In the resulting list, patients whose information has been obtained from inbound HL7 ADT messages will be returned. You will see one line in the table for each message received: unlike the maternal application, a single patient may have many results returned here. Selection of the top-most entry will generally return the most up-to-date and complete message. Select the desired patient.

- Verify the retrieved information and click Finish when complete.

- The census screen will now have your patient listed, as shown in the screen clip above. Selecting that patient and clicking on “Chart”, then “Admission” will open the following screen:

- Notice the fields populated in the screen above; comparing them against the HL7 message at the top of this document, the data source and destination are apparent.
- Where new ADT messages have arrived for a patient, click on the “U” in the census next to their name. On the resulting search screen, uncheck Admit Date Time and Date of Birth search options and click “Search”, to review new messages for incorporation into the patient record.

ORU^R01	Unsolicited Results
MSH	Message Header
PID	Patient Identifier
PV1	Patient Visit Information
ORC	Common Order
{	
OBR	Observation Request
{	
OBX	Observation / Result
[{ **NTE** }]	Notes and Comments
[**SPM**]	Specimen
}	
}	

Laboratory Results

Results are received in unsolicited observation (ORU^R01) messages from LIS systems. This message type is reused for subsequent interface functionality; absent any requisite (and later-described) distinguishing information, received ORU^R01 messages are presumed to be laboratory observations/results.

3.7 Lab Example

The following message was run through the interface engine into PWS (message formatted for legibility):

```
MSH|^~\\&|SendApp2|SendFac2|RecvApp|RecvFac|201101010021||ORU^R01|ADT201947278|P|2.3|||AL||||

```

The PID segment of the passed message must match the MRN, first and last name, and date-of-birth of a patient who has either been manually admitted into PWS or for whom an ADT message exists and has been or will be sent to PWS. Upon arrival of a lab result message for an admitted patient, the census will show an 'L' next to the patient in the "Interface" column.

- Click on this "L" to show the Laboratory Results screen:

- There is a line for each inbound laboratory message – each message may contain one or many actual results. Expand the entries by clicking the ⊞ to see the results themselves; click on the

message row and select “Review” to add the lab result to the patient’s chart. (Lab messages for the patient will not be added to the patient’s medical record within PeriWatch Newborn unless reviewed.)

- To view results which have been reviewed and posted on the chart, right-click on “Lab Results” and select “Show Lab Results records on Flowsheet”

3.8 Segment and Field Definitions

The following tables describe fields directly consumed by PWS. The intention of this section is to describe which fields are actually and directly mapped into (or out of) the PWS application. Fields required by the HL7 standard specification are still required for a message to be considered valid: omission of a field otherwise required by the HL7 standard specification from tables below indicates only that it is otherwise ignored by the PWS interface engine logic.

Unless otherwise noted, any additional subfield breakdowns will default to the first segment (e.g., if XXX.3.2 is noted in the table below but a given message defines subfields within XXX.3.2, XXX.3.2.1 will be utilized by default). If a field may repeat per specification, this field will be notated within the table by either a subscript **0** or **n;** indicating our use of only the first of the repeats and ignoring all subsequent fields or processing all passed repeats, respectively. Thus $AL1_n.5_0$ indicates that all passed allergy segments are processed, but that only the first .5 segment is considered for each AL1 – any subsequent .5 segments in a given AL1 message would be ignored.

All fields are considered of type **String** save **DateTime** fields, which are considered strings but parsed into the XML-defined UTC DateTime format (with GMT-offset presumed equal to that of the host EHR system).

Concerning the capture of an infant's mother's information: $PID.21_0.1$ (Mother's MRN) is populated for infants where available. Where NK1.3 (Relationship) is "MTH" or "MOTHER", the information from this segment is used to prepopulate information regarding the infant's mother. Currently First and Last Name are the only captured values; additional data capture may be possible upon request.
